

Hydraulic Stimulation and Geophysical Fracture Monitoring in the *GeneSys*-Project

J. Orzol⁽¹⁾, R. Jung⁽¹⁾, H. Buness⁽¹⁾, T. Tischner⁽²⁾, R. Jatho⁽²⁾
and P. Kehrer⁽²⁾

(1): GGA-Institute, Hannover; (2): BGR, Hannover

Objective

- supply geothermal heat for direct use
- use one-well concepts

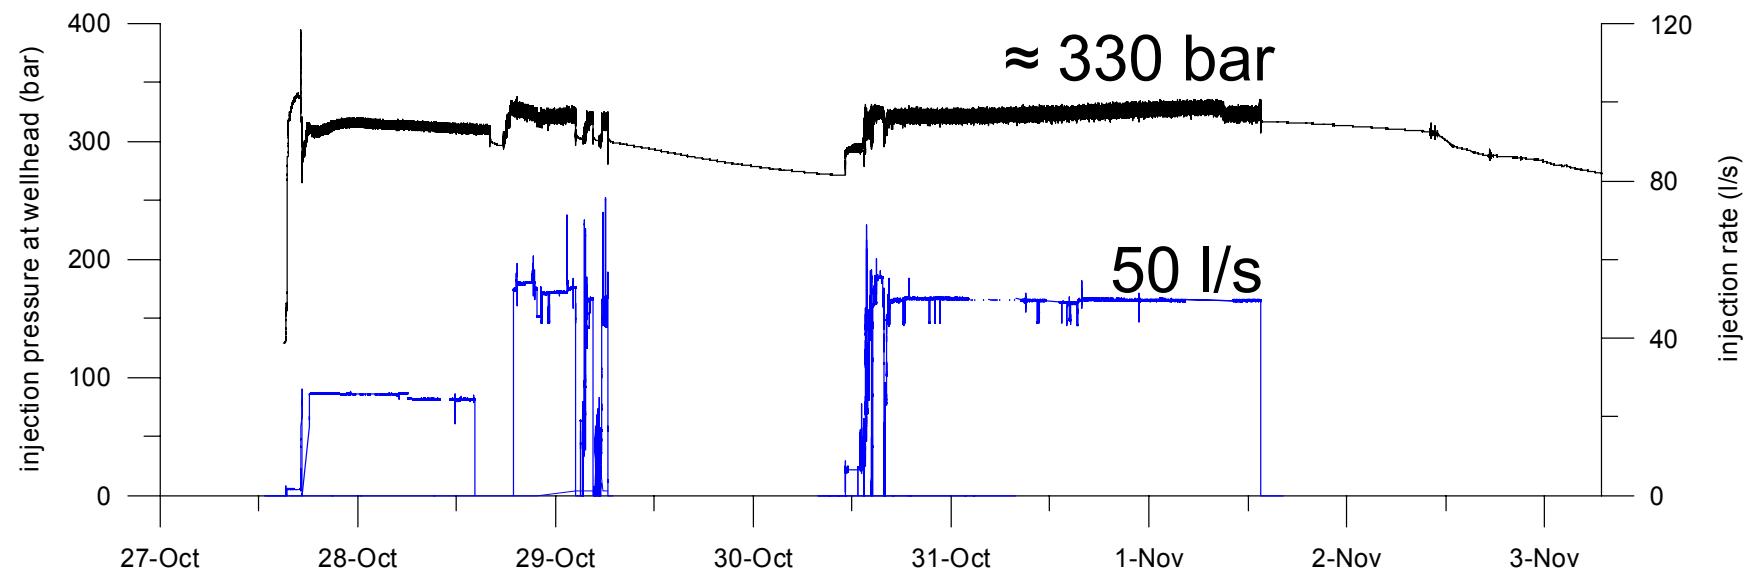

thermal power: 2 MW
flowrate: 25 m³/h
temperature: 130 °C
costs: 7.5 Mio €

GeneSys

- sedimentary rocks
- low porosity & permeability
- create artificial geothermal systems (EGS)
- transfer waterfrac technology to sediments
- Is there a self propping mechanism for sediments?
- fracture propagation in layered sediments?
-

Stimulation operations

- Injection of 20.000 m³ fresh water
- Creation of a large fracture with high conductivity

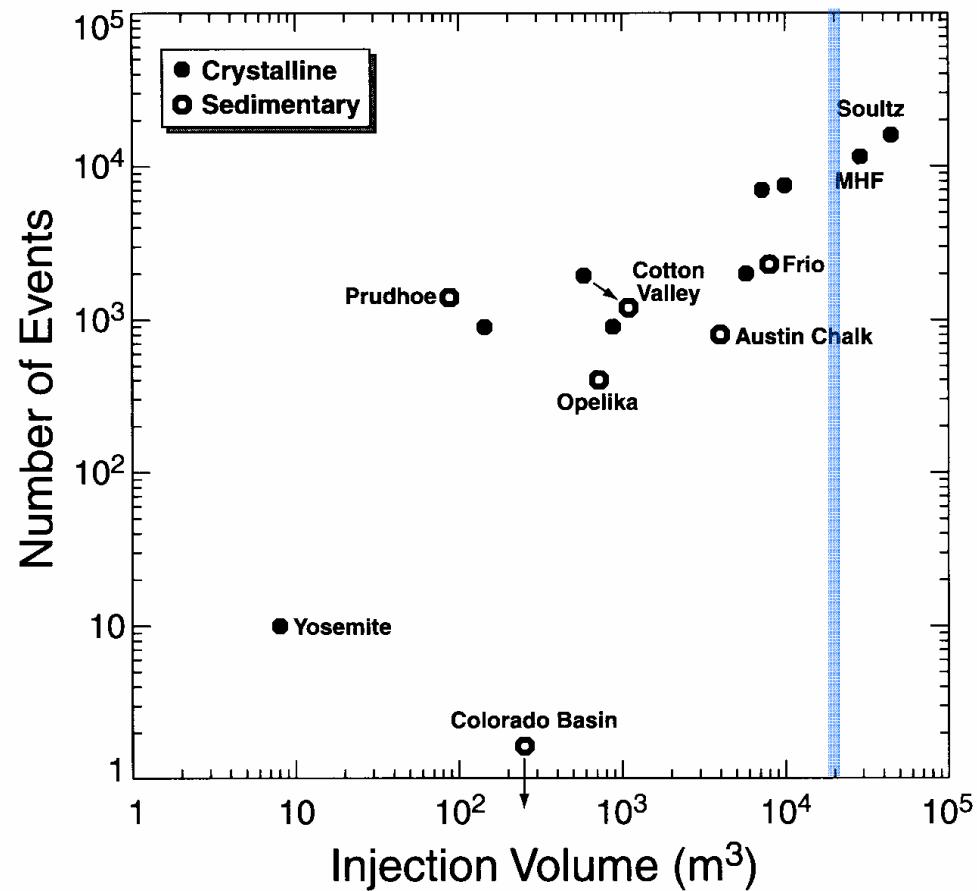

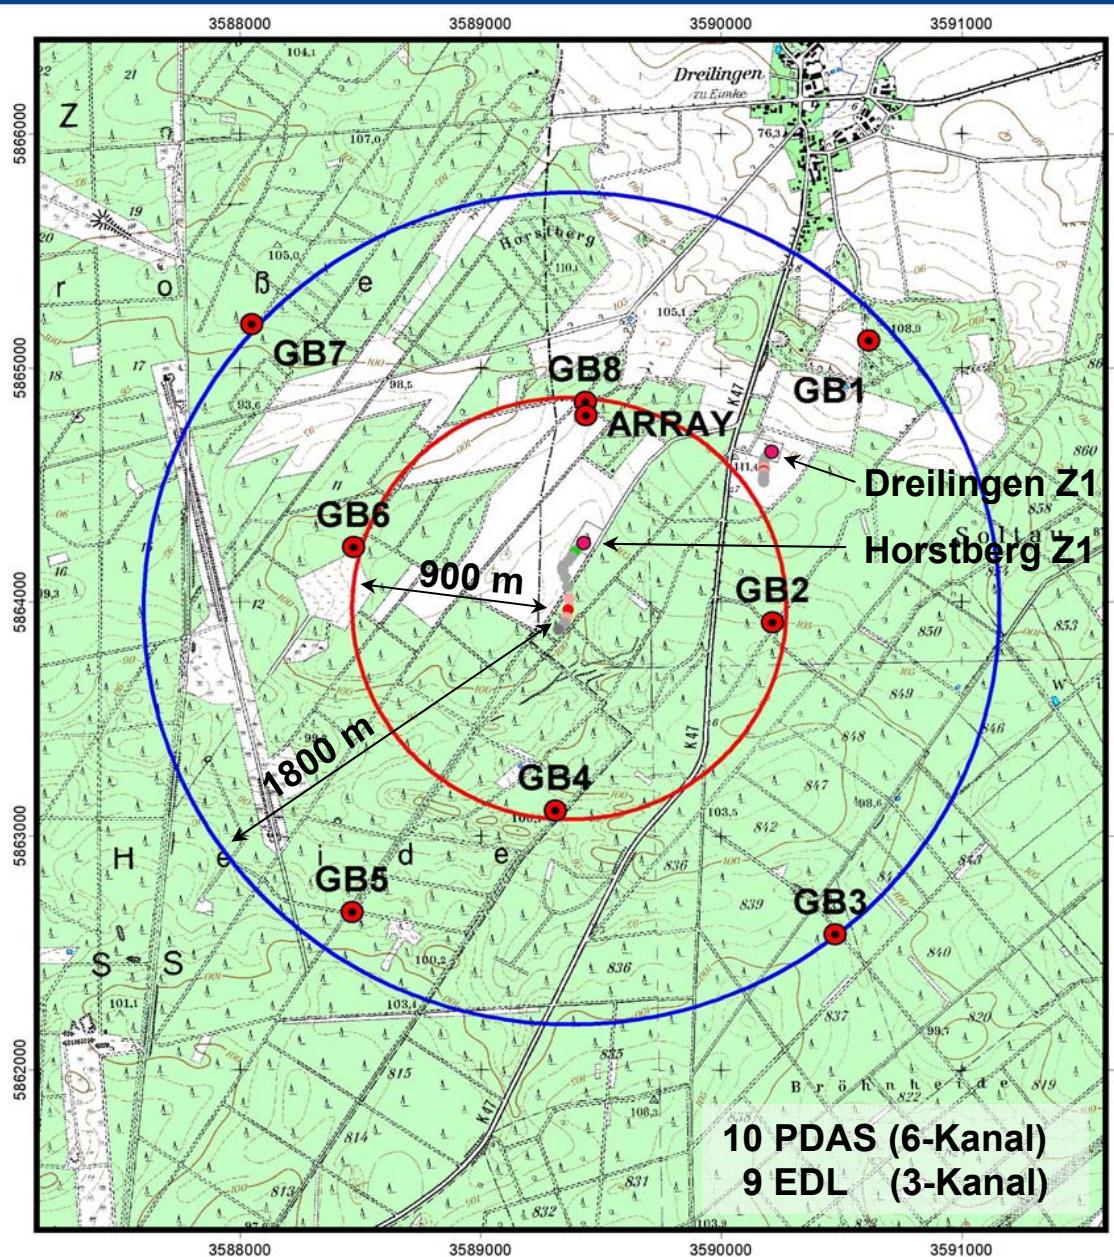

Figure 1

Number of recorded events versus injection volume from a sampling of crystalline and sedimentary reservoir experiments. Crystalline rock experiments are represented by filled circles and include many Fenton Hill injections. Sedimentary experiments are represented by open circles. The Colorado basin experiment produced no observable events, as indicated by an arrow. Results from a Cotton Valley injection coincide with a Fenton Hill experiment, also indicated by an arrow.

**Phillips
et al. 2002**

3 - component 4,5 Hz geophone

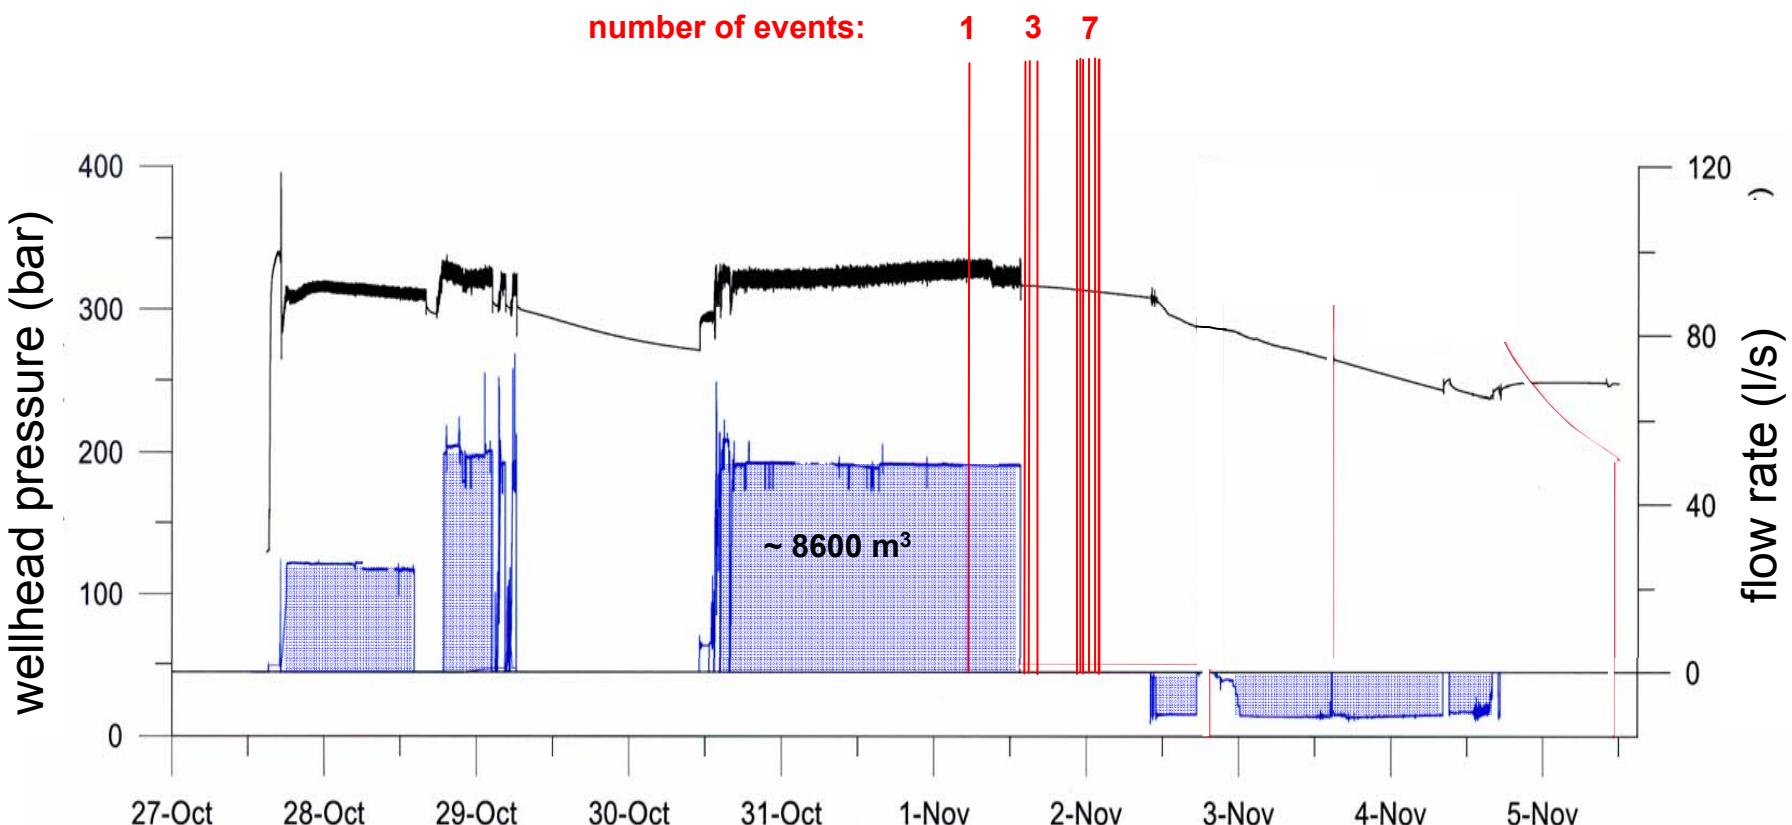

charges (each 30 g)

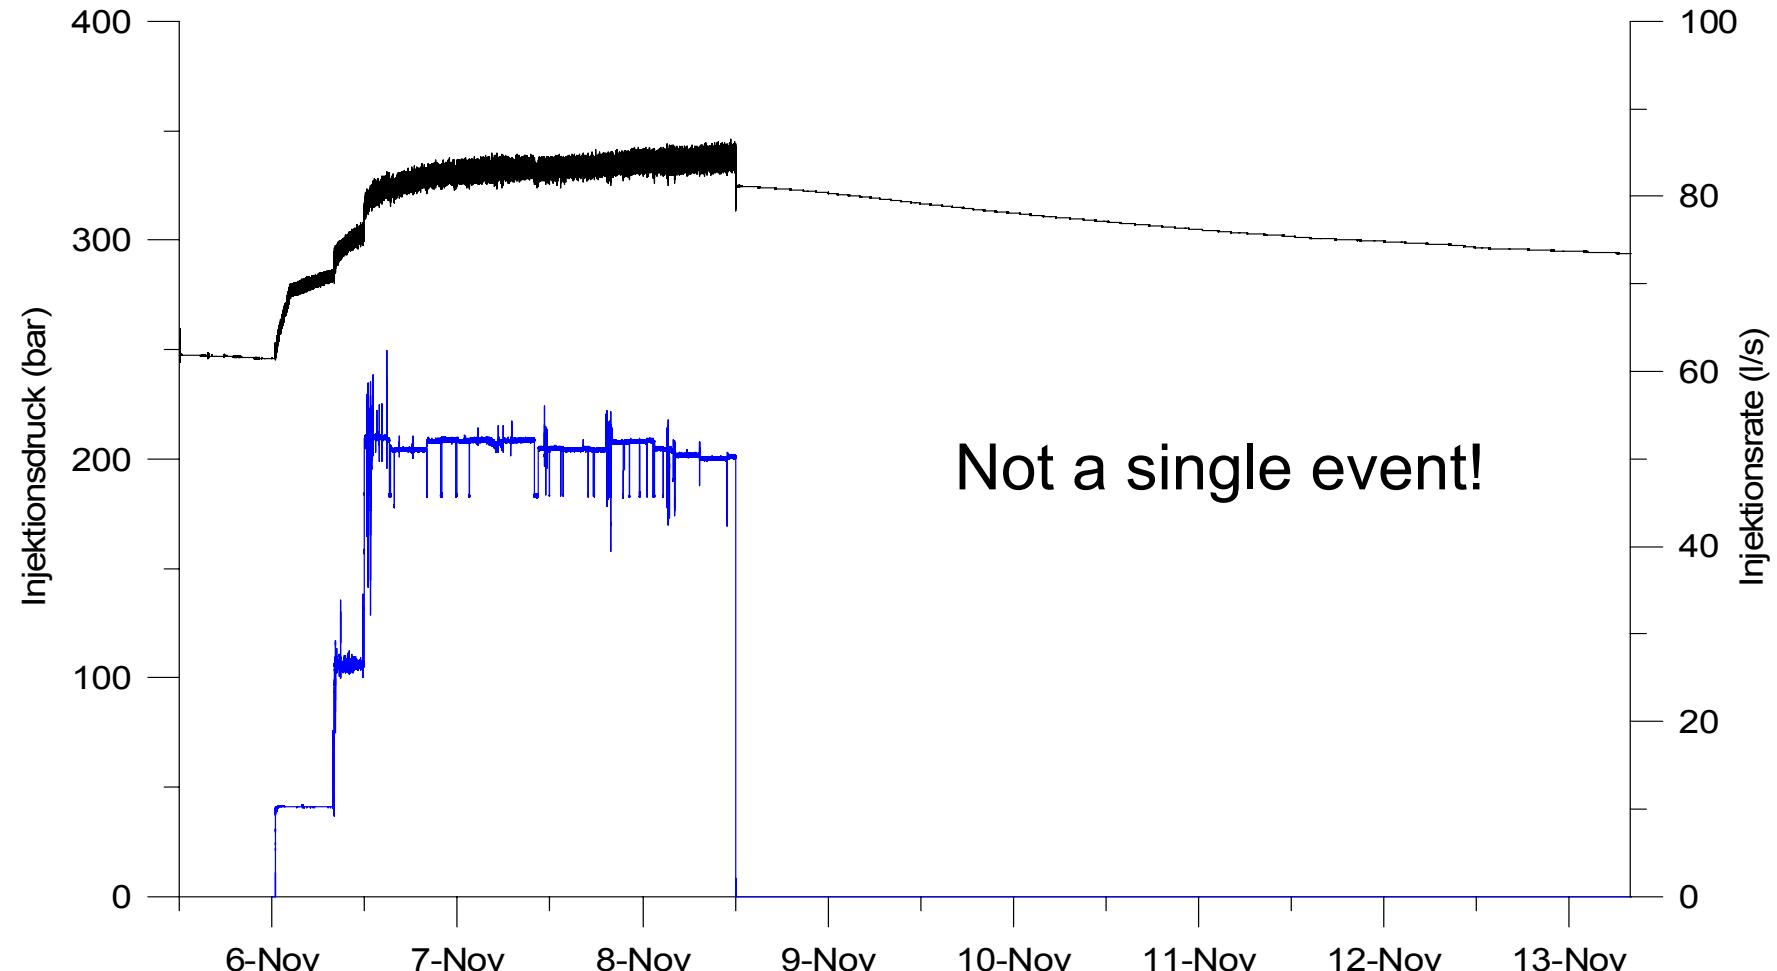

use seismic signals from perforator guns to:

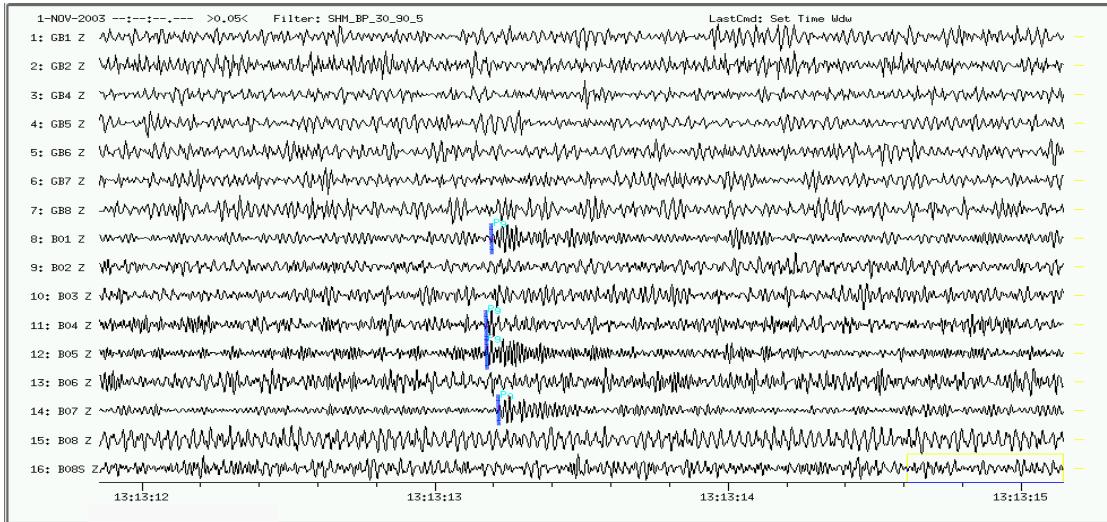

- calibrate velocity model
- estimate detection level (seismic efficiency only vaguely known)
- $M \sim 0.$ to -0.5
(comparable to Soultz)

Induced seismicity – temporal occurrence

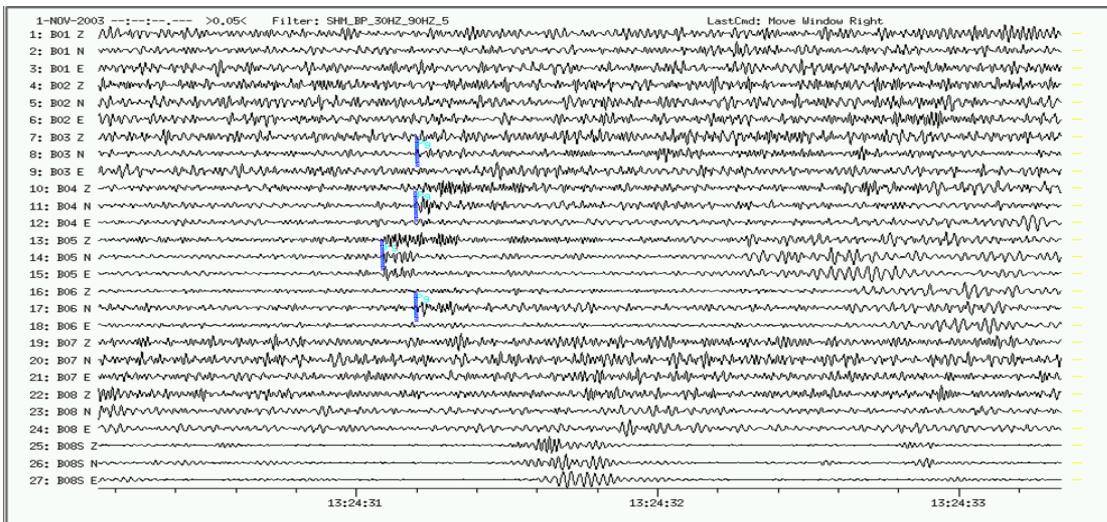

Second Stimulation

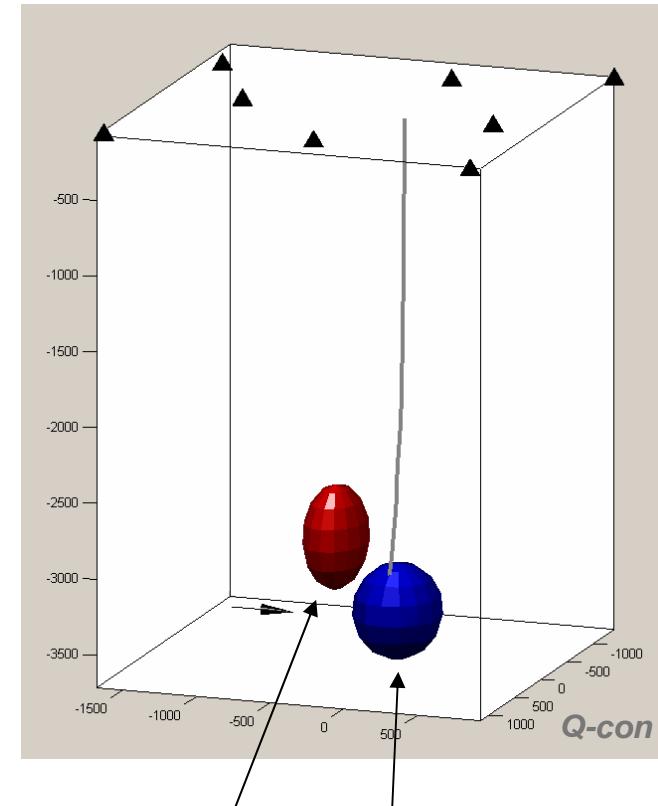

Seismic Event 1.11., 13:13:11. all stations, z-component

Seismic Event 1.11., 13:24:29. EDL - stations, all components, bandpass 30 – 90 Hz.

Event 13:13:11 / 13:24:29

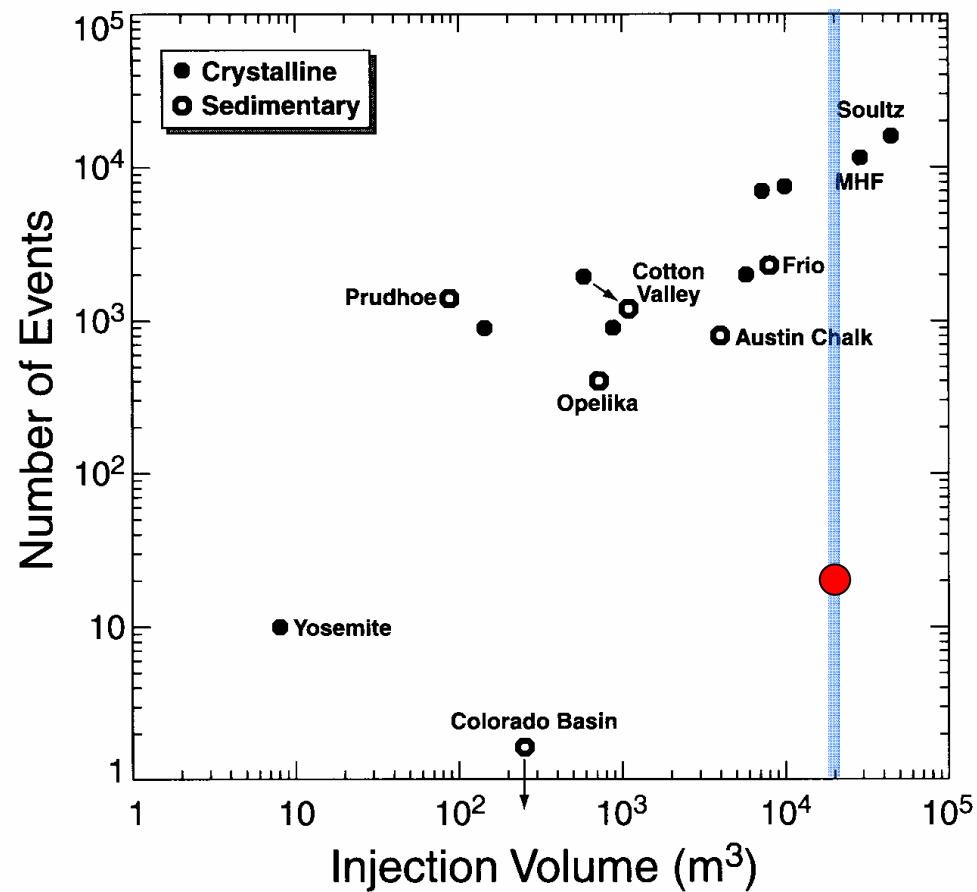

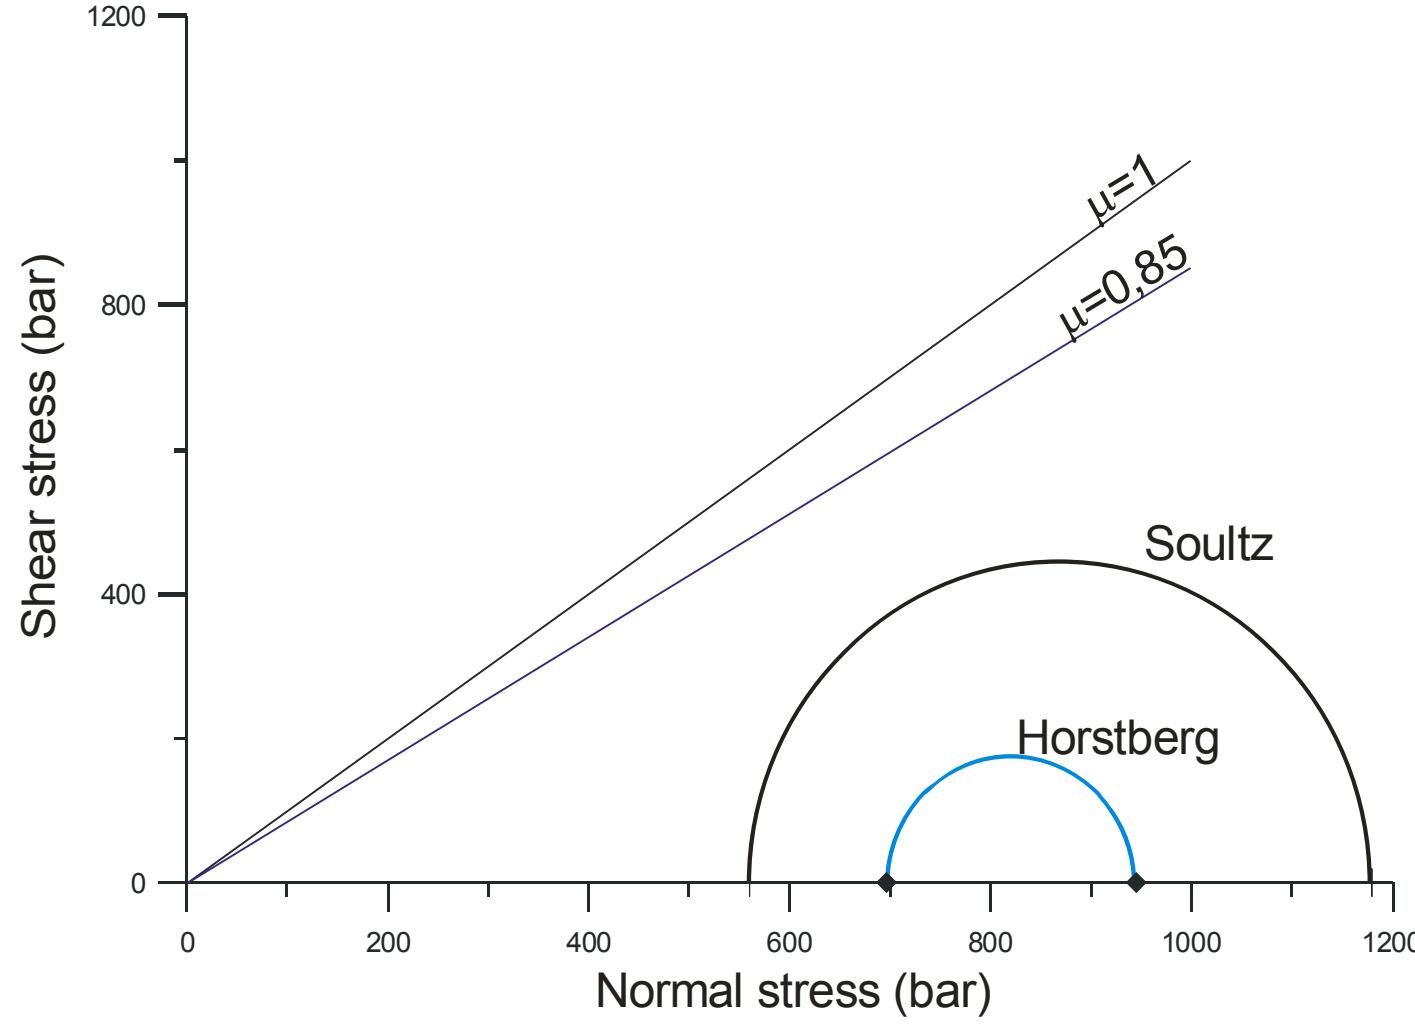

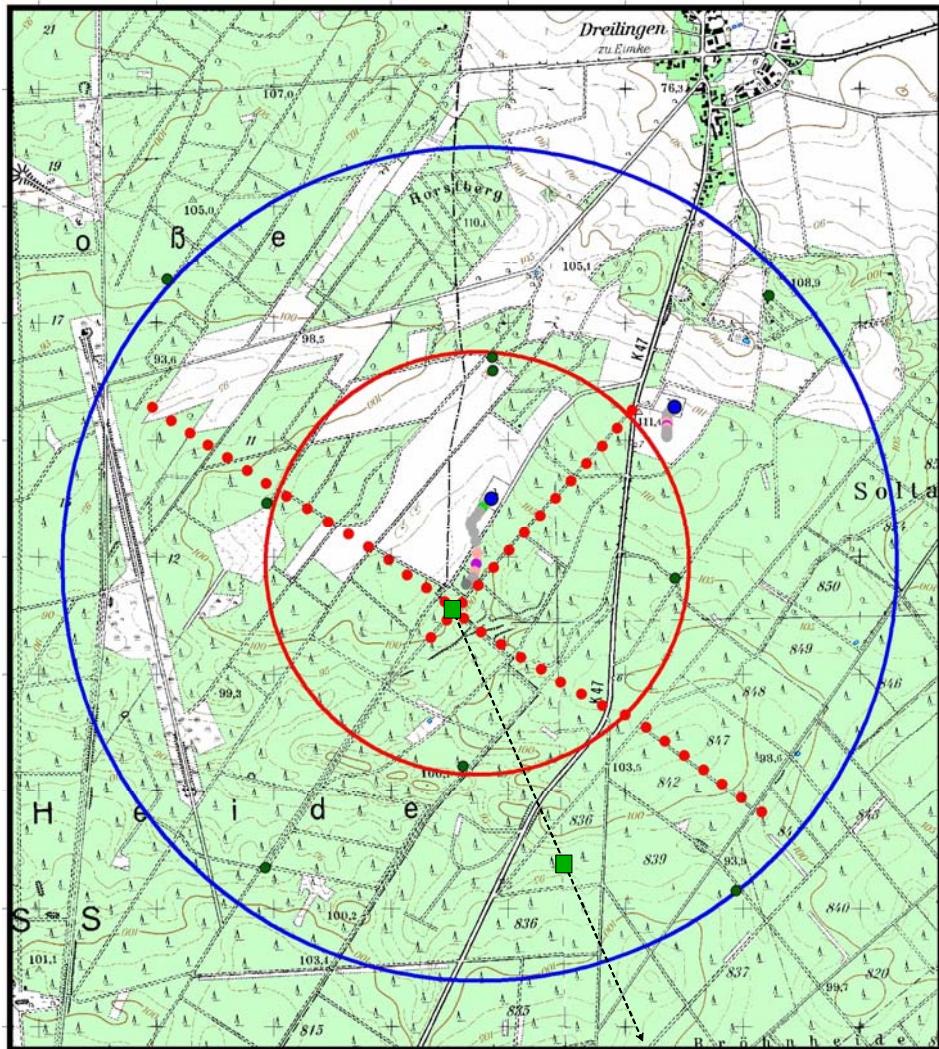

Figure 1

Mohr Circle

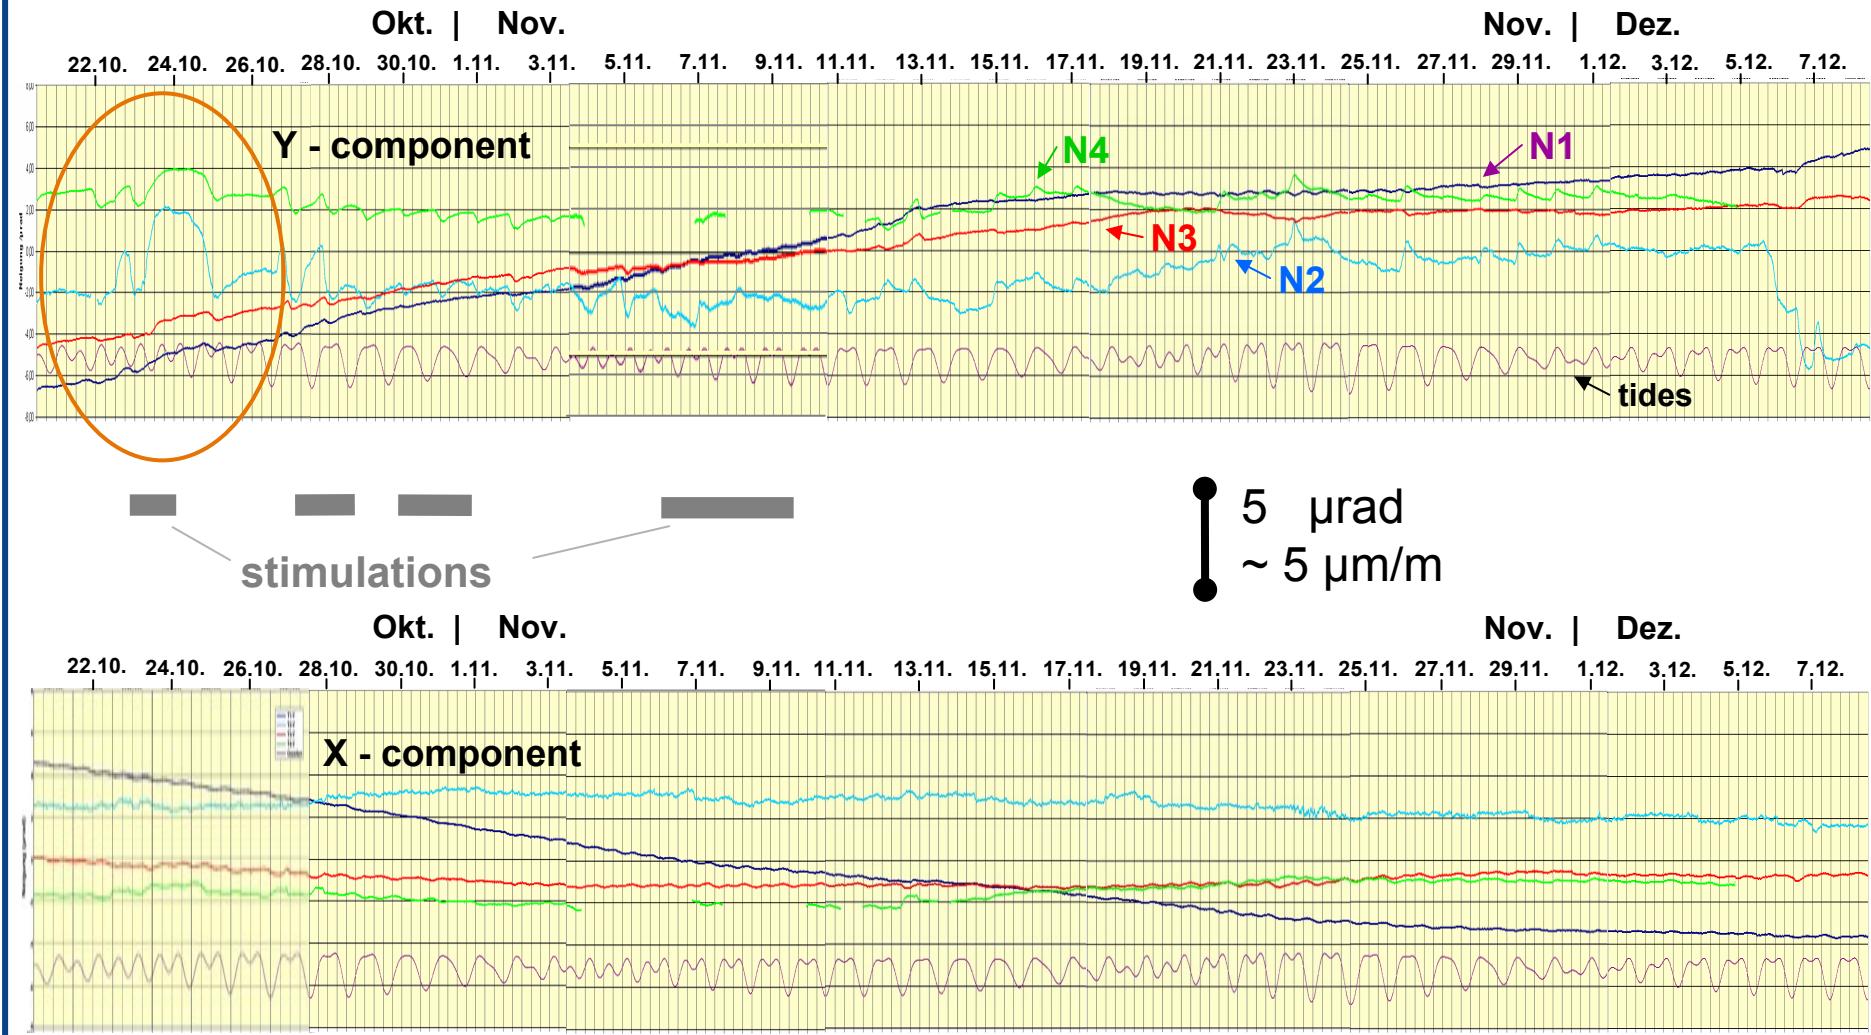

Self-potential & tiltmeter

...no clear correlation to hydraulic activities...

Tiltmeter

outlook

- demonstration project Hannover
- 3.800 m deep well
- massive waterfrac-tests
- installation of a micro-seismic network in preparation

Conclusions/Summary

- propagation of a large tensile fracture by injection of 20.000 m³ of fresh water
- only very few events detected
- Soultz-like events did not occur
- low stress difference between S_h and S_v: presumably no shearing, tensile fracture
- potentially numerous smaller events not detected
- deeper observation wells desirable, but too costly
- more experience from Hannover site 2007/2008

Estimate of fracture height

- fracture clearly propagates through clay stones
- vertical fracture extension approx. 200 m
